Declaration of Authorship

I, Santiago CASAS CASTRO, declare that this thesis titled, "Non-linear structure formation in models beyond LCDM" and the work presented in it are my own. I confirm that:

- This work was done wholly or mainly while in candidature for a research degree at this University.

- Where any part of this thesis has previously been submitted for a degree or any other qualification at this University or any other institution, this has been clearly stated.

- Where I have consulted the published work of others, this is always clearly attributed.

- Where I have quoted from the work of others, the source is always given. With the exception of such quotations, this thesis is entirely my own work.

- I have acknowledged all main sources of help.

- Where the thesis is based on work done by myself jointly with others, I have made clear exactly what was done by others and what I have contributed myself.

Chapter 1

Overview of Standard Cosmology

1.1 The framework of General Relativity

1.1.1 The equivalence principle and geometry

- The equivalence principle

- Manifolds and local flatness

- Physical relation equivalence principle -> local flatness

- The metric formalism

- The Levi-Civita connection

- Dipheomorphism invariance

1.1.2 The Einstein-Hilbert action and the field equations

$$S = \int \mathrm{d}x^4 \sqrt{-g}(R - \Lambda) \tag{1.1}$$

$$R_{\mu\nu} + \frac{1}{2}g_{\mu\nu}R + g_{\mu\nu}\Lambda = 8\pi G T_{\mu\nu} \tag{1.2}$$

- Bianchi identities and the conservation of $T_{\mu\nu}$

- Lovelock's theorem

1.1.3 The Newtonian limit

- Gravitational potentials Φ and Ψ.

- Very simple explanation of Gauge choice

- Newtonian Gauge

- Smallness of gravitational potentials

- Remark for later that in GR $\Psi = \Phi$

- Weyl potential (lensing potential, null geodesics)

1.2   The standard cosmological model

- small discussion on how to define a cosmology

- Observer along timelike geodesic and foliation of spacetime

1.2.1   Friedmann equations

- Friedmann-Lemaître-Robertson-Walker metric

- 00 and ii components of Einstein equation

- First and second Friedmann equations

- Several ways of writing Hubble function for different species

- Background expansion, , RDE, MDE, w(z)

1.2.2   Distances

- definition of distances

- definition of Hubble time

- Horizons?

1.2.3   The ΛCDM paradigm

- Reasons for CDM

- Reasons for Lambda

- Baryons, neutrinos and other species

1.2.4   The cosmological constant problem

- small discussion on old and new cosmological constant problem

- fine tuning, naturalness, basic definitions

1.2.5   Linear perturbations

- Differentiate between linear perturbations in different eras, just shortly

- Linear perturbations in matter dominated eras, newtonian gauge

- Fluid equations, full and linearized

1.3   Early Universe

1.3.1   Cosmic Microwave Background Radiation

- Short introduction and importance of CMB

- Important constraints on parameters coming from CMB

- Constrain CDM alone

- Constrain initial power amplitude and tilt

- Constrain relativistic degrees of freedom

1.3.2   Inflation

- Inflation as a paradigm

- Flatness and horizon problems

- Inflation produces almost scale invariant spectrum

Chapter 2

Dark Energy and Modified Gravity

2.1 Universal coupling to matter

- define Jordan and Einstein frame

- write action in both cases

- write that in Universal coupling matter couples to the full $\sqrt{-g}$

2.1.1 Quintessence

- small introduction to quintessence, Ratra, Peebles, Wetterich, Luca

- different potentials, Brans-Dicke, Exponential potential

2.1.2 f(R) Theories

- small intro to f(R), Amendola, Felice, Tsujikawa

- write f(R) as conformal transformation of quintessence (Valeria's paper)

2.1.3 Horndeski Theory

- Most general single scalar field theory, second order equations of motion, 4 dimensions, ghost-free

- 5 Lagrangians which can be parametrized with the α functions that give more physical insight.

- Quasistatic limit yields modifications of gravity that depend only on time and k^2.

In a homogeneous and isotropic universe, the distance element assumes the form:
$$ds^2 = a(\tau)[-(1+2\Psi)d\tau^2 + (1-2\Phi)\delta_{ij}dx^i dx^j], \qquad (2.1)$$

where the conformal time τ is related to the cosmic time t by $d\tau = dt/a(\tau)$ and Ψ and Φ are the two scalar gauge invariant gravitational potentials, related (modulo sign) to the Bardeen potentials.

Horndeski models include (almost) all theories with second order equations of motion in the fields and can be generically described with five functions of time. They include a variety of particular models studied in literature, characterised by a universal coupling to matter fields.

The Lagrangian can be written as ...

where ... is the matter Lagrangian and ... are arbitrary functions of the scalar field ϕ, whose canonical kinetic term is $X = -\frac{1}{2}\phi^{;\mu}\phi_{;\mu}$; the latter is also coupled to the Ricci scalar and the Einstein tensor.

In the following, we will adopt the conformal Newtonian gauge in the notation of (**MaBertschinger**), so that the gauge invariant potentials Ψ and Φ are also equal to the gravitational potentials in the Newtonian limit. In this formulation, the cold dark matter (CDM, c) perturbation equations for the density contrast δ and the velocity divergence θ can be written in Fourier space in the usual way:

$$\dot{\delta}(\tau, \mathbf{k}) = -(\theta(\tau, \mathbf{k}) - 3\dot{\Phi}(\tau, \mathbf{k})) \;, \tag{2.2}$$

$$\dot{\theta}(\tau, \mathbf{k}) = -H\theta(\tau, \mathbf{k}) + k^2\Psi(\tau, \mathbf{k}) \;. \tag{2.3}$$

Derivating the first of the above equations with respect to τ and eliminating $\dot{\theta}$ and θ using both equations, one obtains the usual second order equation in time for the density contrast:

$$\ddot{\delta}(\tau, \mathbf{k}) = -(H\dot{\delta}(\tau, \mathbf{k}) - 3H\dot{\Phi}(\tau, \mathbf{k}) + k^2\Psi(\tau, \mathbf{k}) - 3\ddot{\Phi}(\tau, \mathbf{k})) \;. \tag{2.4}$$

In the following, we will stay within the quasi-static limit, i.e restrict to scales much smaller than the cosmological horizon ($k/aH \gg 1$) and well inside the Jeans length of the scalar field $c_s k \gg 1$, so that terms containing k dominate over terms containing time derivatives. In this case, Eq. 2.4 reduces to:

$$\ddot{\delta}(\tau, \mathbf{k}) + H\dot{\delta}(\tau, \mathbf{k}) + k^2\Psi(\tau, \mathbf{k}) = 0 \,. \tag{2.5}$$

The gravitational potential is then obtained from the Poisson equation, that relates the gravitational potential to matter and relativistic species in the universe, by perturbing the Einstein field equations to first order.

In Horndeski theories, in the quasi-static limit, the deviation of the gravitational potentials from General Relativity has a known scale dependence in the Poisson equation, given by (**...**):

$$\mu(k, a) \equiv -\frac{2k^2\Psi}{3\Omega_m\delta_m} = h_1\left(\frac{1 + (k/k_*)^2 h_5}{1 + (k/k_*)^2 h_3}\right) \tag{2.6}$$

where h_1, h_3, h_5 are functions of time only. A similar expression, with different time dependent coefficients h_2, h_4, holds for the gravitational slip η:

$$\eta(k, a) \equiv -\frac{\Phi}{\Psi} = h_2\left(\frac{1 + (k/k_*)^2 h_4}{1 + (k/k_*)^2 h_5}\right) \;. \tag{2.7}$$

In this work we will consider all h_i functions as constants, for simplicity, although in general they are all functions of time. k_* is an arbitrary pivot scale, chosen at large scales close to the horizon, in order to fulfil the quasi-static limit.

As it can be seen from eqns. 2.6 and 2.7, the functions h_5 and h_3 are degenerate as well as h_4 and h_5. ΛCDM case is recovered when $\mu = \eta = 1$,

which implies $h_5 = h_4 = h_3$ and an amplitude $h_1 = h_2 = 1$.

In the following, we will focus on CDM perturbations and deal only with the function $\mu(k, a) = \mu(k)$ (although perturbations require two functions of time and scale to fully specify the model). In particular, we will test the following cases:

1. Scale independent μ with modified amplitude: $h_5 = h_3$ and $h_1 > 1$ or $h_1 < 1$.

2. Scale dependent μ with unity amplitude: $h_1 = 1$ and $h_5 > h_3$ or $h_5 < h_3$.

3. Scale dependent μ with modified amplitude: $h_1 \neq 1$ and $h_5 > h_3$ or $h_5 < h_3$.

In logarithmic space $\mu(k)$ is very close to a step function, as shown in figure **??**, so that we will only use values for the h_i in which the difference of the minimum and the maximum is of the order of 15%, since otherwise we would impose a rather unrealistic structure formation.

2.1.4 Effective Field Theory of Dark Energy

- Another approach to construct a general model for dark energy based on the allowed symmetries in the action.

- Can be parametrized with the α functions.

- Allows in a simple way to create theories beyond Horndeski and to accomodate non-universal couplings.

2.2 Non-universal coupling

- Motivate dark energy, the coincidence problem and a dark sector interaction

- Explain why baryons should be uncoupled (Solar system constraints)

2.2.1 Coupled Dark Energy

- Introduce coupling at the energy momentum tensor

- Linear perturbations, gravitational bias DM-baryons, signatures in LSS, non-linear perturbations

- Talk about present constraints

2.2.2 Growing Neutrino Quintessence

- Motivate coupling to neutrinos (energy scale of DE and coincidence problem), particle physics seesaw mechanism perspective, non-relativistic neutrinos

- Background equations, linear perturbations and instabilities, failure of linear theory to take into account structures, lumps and backreaction

- Non-linear perturbations, simulations, neutrino lump dynamics, heating of neutrinos

2.2.3   Non-universal couplings in EFT

Paper by Gleyzes

Chapter 3

Observables and Experiments in Cosmology

- Can be split roughly into two big categories and each one into smaller categories. (not taking into account more futuristic probes)

- The two big categories are: Early Universe and Late Universe.

- In the Early Universe there is the CMB temperature map, the CMB polarization maps and Big Bang Nucleosynthesis constraints. Soon there will be Gravitational Wave Background constraints.

- In the late universe there are broadly two categories: Background expansion and Structure formation.

- Background expansion includes: distance-redshift measurements, geometric measurements

- Structure formation includes: Galaxy Clustering, Weak Lensing, CMB Lensing.

3.1 Clustering of galaxies

- Important observable is the two point correlation function of galaxy positions and its Fourier transform, the power spectrum.

- Galaxies are supposed to trace the distribution of dark matter density. The difference between galaxy density distribution and DM distribution is called the bias.

- Galaxy clustering measures effectively the Poisson equation and therefore δ and modifications to it. Through BAO measurements and redshift bins it also measures the growth rate f and geometrical quantities such as H and D_A.

- The linear power spectrum can be calculated exactly, while at small scales (large k) the non-linearities coming from the Vlasov-Poisson system become important.

3.2 Weak gravitational lensing

- The fundamental observable is the Weyl Power spectrum, which is the power spectrum of the Weyl potential $\Phi + \Psi$.

- The Weyl power spectrum can on one side be related to the matter density fluctuations for a specific model that depends and on the other side it is related to the shear and convergence maps of the distortion of galaxy shapes.

- Weak lensing is a powerful measurement of large scale structure, since it is directly sensitive to dark matter and does not depend on details of baryon formation. On the other hand, it does not give so much information about geometrical quantities or the ratio between Ω_b and Ω_c.

- It can be contaminated with lots of systematics, like intrinsic alignments and instrument noise. For being useful, it needs a well determined non-linear matter power spectrum.

3.3 Future Experiments

3.3.1 Euclid

- This space mission will measure ~100 Million spectroscopic redshifts of galaxies and ~10^9 photometric images of galaxies.

- It will be a galaxy Clustering and Weak Lensing probe. Combining both observations it will yield unprecedented constraints on cosmological parameters.

- For using all its data, we will need to be able to calculate the linear and non-linear matter power spectrum in many different cosmological models.

- The fiducial bias and other systematics have to be removed by doing N-body and End-to-End simulations.

3.3.2 SKA 1 & 2

- SKA1 will be the first stage of an array of radio telescopes. Among many interesting observations, it is capable of measuring redshifts and shapes of galaxies.

- SKA2 will be a major upgrade planned for >2025.

- It strength will be that it not only determines Galaxy Clustering and Weak Lensing, but also its cross-correlation with more futuristic probes, like Ly-alpha and Intensity mapping.

3.3.3 DESI

- It is a ground based observation and will be able to measure millions of redshifts of galaxies.

- It can discriminate between bright galaxies, red galaxies and quasars.

- It will only be useful for Galaxy Clustering.

Statistics in Cosmology

4.1 Correlation functions and the power spectrum

- Gaussian random variables

- Statistical isotropy and homogeneity

- Correlation functions and power spectrum

4.2 Likelihood and the Bayesian approach

- Bayes Theorem

- Likelihood

- Priors, posteriors and evidence

4.3 Fisher Matrix formalism

- Approximation of the Gaussian likelihood at the minimum

- Ellipses and confidence contours

- Marginalization and maximation

4.4 The Fisher Matrix Code

- This serves as a manual for the Fisher Tools code.

4.4.1 Methodology of Fisher forecasts

- Derivatives of cosmological functions

- Integration or summation in k or ℓ space

- Alcock-Paczynski effect

- Redshift binning

- Shape, redshift and nuisance parameters

- Marginalization

4.4.1.1   The observed power spectrum

The observed power spectrum is built from the theoretical power spectrum $P(k, z)$ which depends on a vector of fundamental cosmological parameters θ_i and the following contributions:

1. The contribution from redshift space distortions and bias $b(z)$, known as the Kaiser formula, where $\beta(z) = f(z)/b(z)$ and $f(z)$ is the growth rate of density perturbations. Terms shown in green below.

2. The geometrical effect of the change of cosmological parameters (the so called Alcock-Paczynski-effect), where $H(z)$ is the hubble function and $D_A(z)$ is the angular diameter distance evaluated at a different set of cosmological parameters as $H_{fid}(z)$ and $D_A(z)_{fid}$ which are defined at the fiducial parameter values (the ratio $H_{fid}(z)/H(z)$ is clearly 1 if both are evaluated at the fiducial values). If this effect is taken fully into account, then k and μ also have to be affected by a geometrical term when evaluating the power spectrum at a different set of parameters. (see the AP-effect section **??** below). These terms are shown in red below.

3. The damping due to redshift errors σ_z and non-linear peculiar velocity dispersions $\sigma_v(z)$, which is the first order correction term to the Kaiser formula. Terms shown in magenta below.

4. Extra shot noise due to observational effects, which can be included in general with the term $P_s(z)$. Term in blue below.

$$P_{\mathrm{obs}}(z, k, \mu; \theta) = P_{\mathrm{s}}(z) + \frac{D_A^2(z)_{ref} H(z)}{D_A^2(z) H(z)_{ref}} b^2(z) \left(1 + \beta(z)\mu^2\right)^2 P(k, z) e^{-k^2 \mu^2 (\sigma_z^2/H(z) + \sigma_v^2(z))}$$

$$(4.1)$$

If one wishes to place constraints on the normalization of the power spectrum, σ_8, then $P(k, z)$ can be written as:

$$P(k, z) = \sigma_8^2 \tilde{P}(k, z) \tag{4.2}$$

where $\tilde{P}(k, z)$ is the normalized power spectrum. The normalization s_R of the power spectrum (which is equivalent to the variance smoothed over a scale R) is given by:

$$s_R = \frac{1}{2\pi^2} \int_{k_{min}}^{k_{max}} k^2 P(k, z = 0) W_R^2(kR) \tag{4.3}$$

The window function smoothes $P(k, z)$ over the scale R and has the form: $W(x) = 3(\sin(x) - x\cos(x))/x^3$, where x is a dimensionless variable. This term comes from assuming spherical symmetry and performing the angle integration of the 3-D power spectrum $P(\vec{k})$. If one chooses $R = 8h^{-1}\mathrm{Mpc}$ and $[k] = \mathrm{h/Mpc}$, then we recover the usual $s_R = \sigma_8^2$. The normalization σ_8 is a quantity defined only in linear theory, which means that in eqn. **??** either $P(k, z)$ is linear or the integration limits are chosen in such a way that only the linear normalization is taken into account, so that usually one should take $k_{max} \approx 0.1$. The normalized power spectrum is simply:

$$\tilde{P}(k, z) = \frac{1}{s_R} P(k, z) \tag{4.4}$$

Due to the of the fact that σ_8 is a linear quantity, we can use it as an independent cosmological parameter, because we can rescale it arbitrarily before it is compared with observations. It is then completely degenerate with the initial primordial amplitude of the power spectrum, $\mathcal{A}_s$, and one can replace one parameter by the other, fixing just one of both.[1]

Furthermore if one wishes to express a linear power spectrum $P(k, z)$ in terms of the primordial power spectrum, the growth $G(z)$ and the transfer functions $T(k)$, one can write eqn. **??** as:

$$P(k, z) = \frac{\sigma_8^2}{s_R} G^2(z) T^2(k) k^{ns} \mathcal{A}_s \tag{4.5}$$

being careful to take either σ_8 or $\mathcal{A}_s$ as a primordial parameter and not both. In the case in which $\mathcal{A}_s$ is the cosmological parameter, the ratio $\frac{\sigma_8^2}{s_R}$ should be 1. The growth function $G(z)$ depends on the cosmological parameters θ_i and is defined to be normalized to unity today: $G(z = 0) = 1$. The quantity $\sigma_8^2 G^2(z) \equiv \sigma_8(z)$ can be defined accordingly and can be used as an independent and time-dependent cosmological parameter too.

4.4.1.2 Derivatives of the observed power spectrum

For the calculation of the Fisher matrix, one needs to take derivatives of the logarithm of the observed power spectrum $P_{obs}(k, z, \mu)$ at the central value $\bar{z}$ of each redshift bin. (see equation for the Fisher matrix). There are two options here in terms of the practical and numerical approach:

- One calculates numerically:

$$\left. \frac{\mathrm{d} \ln P_{\mathrm{obs}} \left(\bar{z}, k, \mu; \theta_i \right)}{\mathrm{d}\theta_i} \right|_{fid} = \frac{P_{\mathrm{obs}} \left(\bar{z}, k, \mu; \theta_i^+ \right) - P_{\mathrm{obs}} \left(\bar{z}, k, \mu; \theta_i^- \right)}{2\varepsilon \theta_i^{fid} \times P_{\mathrm{obs}} \left(\bar{z}, k, \mu; \theta_i^{fid} \right)} \tag{4.6}$$

where θ_i^+, θ_i^- represent the parameter θ_i evaluated at $\pm\varepsilon$ around the fiducial value θ_i^{fid}:

$$\theta_i^{\pm} = \theta_i^{fid}(1 \pm \varepsilon) \tag{4.7}$$

However this assumes that all functions inside $P_{\mathrm{obs}}(\bar{z}, k, \mu; \theta_i)$ can be evaluated at $\theta_i^{\pm}$. Since this is not the case for the bias $b(z)$, one needs to add a further intermediate variable (see section **??** below on marginalization).

---

[1] One has to emphasize that this can only be done for linear power spectra, because if one takes nonlinear density fluctuations into account for calculating a non-linear $P(k, z)$, a different primordial amplitude of fluctuations has a non-linear effect at small scales in the so called "non-linear bump". The degeneracy between $\mathcal{A}_s$ and σ_8 is then broken.

- One uses intermediate variables, namely the functions in eqn. **??**, which depend on θ_i, and with the help of the chain rule one can write:

$$
\left.\frac{\mathrm{d}\ln P_{\mathrm{obs}}\left(\bar{z},k,\mu;\theta_i\right)}{\mathrm{d}\theta_i}\right|_{fid} = \frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln P_s(\bar{z})}\frac{\partial \ln P_s(\bar{z})}{\partial \theta_i} + \frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln f(\bar{z})}\frac{\partial \ln f(\bar{z})}{\partial \theta_i}
$$
$$
+ \frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln H(\bar{z})}\frac{\partial \ln H(\bar{z})}{\partial \theta_i} + \frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln D_A(\bar{z})}\frac{\partial \ln D_A(\bar{z})}{\partial \theta_i}
$$
$$
+ \frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln P(k,\bar{z})}\frac{\partial \ln P(k,\bar{z})}{\partial \theta_i} + \frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln b(\bar{z})}\frac{\partial \ln b(\bar{z})}{\partial \theta_i}
$$
$$
(4.8)
$$
$$
+ \frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial k}\frac{\partial k}{\partial \theta_i} + \frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \mu}\frac{\partial \mu}{\partial \theta_i}
$$

where we have ignored the dependence on the damping terms of eqn. **??** for simplicity. The last two terms are non-vanishing if one takes the Alcock-Paczynski effect into account for k and μ, since they are affected by geometrical terms also (see AP-effect section **??** below).

One then has to calculate the intermediate derivatives of $\ln P_{obs}(z,k,\mu;\theta_i)$ with respect to P_s, D_A, H, f and b using eqn. **??**. The logarithm of these quantities is used, because it simplifies considerably the equations. Notice that the growth $G(z)$ is inside the definition of $P(k,z)$ so it is not needed as an intermediate variable, however it can be also used if wanted. It is important to stress here that the derivatives are calculated at the *fiducial* value of the parameters, including the fiducial values of the cosmological functions. The fiducial value of the shot noise is zero, $P_s^{fid}(z) = 0$. And under this choice the derivatives are:

$$
\frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln P_s(\bar{z})} = \frac{1}{P_{obs}\left(\bar{z},k,\mu;\theta_i\right)} \tag{4.9a}
$$
$$
\frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln f(\bar{z})} = \frac{2\beta(\bar{z})\mu^2}{1+\beta(\bar{z})\mu^2} \tag{4.9b}
$$
$$
\frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln b(\bar{z})} = \frac{2}{1+\beta(\bar{z})\mu^2} \tag{4.9c}
$$
$$
\frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln H(\bar{z})} = 1 \tag{4.9d}
$$
$$
\frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln D_A(\bar{z})} = -2 \tag{4.9e}
$$
$$
\frac{\partial \ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial \ln P(k,\bar{z})} = 1 \tag{4.9f}
$$

If for the moment and for simplicity we neglect the extra shot noise contribution P_s and the dependence of k and μ on the change of cosmological parameters (see AP-effect section below) we get for each derivative of $P_{obs}(k,\mu,z)$ with respect to a cosmological parameter θ_i:

$$\frac{\mathrm{d}\ln P_{\mathrm{obs}}\left(\bar{z}, k, \mu; \theta_i\right)}{\mathrm{d}\theta_i}\bigg|_{fid} = \frac{\partial \ln P(k, \bar{z})}{\partial \theta_i} + \frac{\partial \ln H(\bar{z})}{\partial \theta_i} - 2\frac{\partial \ln D_A(\bar{z})}{\partial \theta_i}$$
$$+ \frac{2\beta(\bar{z})\mu^2}{1 + \beta(\bar{z})\mu^2}\frac{\partial \ln f(\bar{z})}{\partial \theta_i} + \frac{2}{1 + \beta(\bar{z})\mu^2}\frac{\partial \ln b(\bar{z})}{\partial \theta_i} \tag{4.10}$$

We see that by using intermediate variables, the space of parameters to be evaluated for the Fisher matrix has been extended by 4 new terms (they could be more if P_{obs} depends on further cosmological functions):

$$\zeta = \{1, 1, -2, \frac{2\beta(\bar{z})\mu^2}{1 + \beta(\bar{z})\mu^2}, \frac{2}{1 + \beta(\bar{z})\mu^2}\} \tag{4.11}$$

The new "vector" of derivatives has the form:

$$\Theta = \{\frac{\partial \ln P(k, \bar{z})}{\partial \theta_i}, 1, -2, \frac{2\beta(\bar{z})\mu^2}{1 + \beta(\bar{z})\mu^2}, \frac{2}{1 + \beta(\bar{z})\mu^2}\} \tag{4.12}$$

notice that θ_i is a vector also, so that this vector has a number of components equal to: $\dim(\Theta) = \dim(\theta) + 4$.

Since the Fisher matrix is a tensor product of a vector od derivatives, we can express it as:

$$F_{ij} \approx \frac{\mathrm{d}\ln P_{\mathrm{obs}}}{\mathrm{d}\theta_i}\frac{\mathrm{d}\ln P_{\mathrm{obs}}}{\mathrm{d}\theta_j} \approx (\Theta \otimes \Theta)_{ij} \tag{4.13}$$

However this is only valid at one single redshift bin and if one wants to add together Fisher matrices at different redshift bins, one has to take into account that each $D_A(\bar{z}_i)$, $H(\bar{z}_i)$, $f(\bar{z}_i)$ and $b(\bar{z}_i)$ is an independent parameter but we will come to that later.

4.4.1.3   Projecting back to the fundamental cosmological parameters

If one wishes to express the Fisher matrix just in terms of fundamental cosmological parameters again, then one needs to perform the variable transformation back using a so-called Jacobian. This can be seen more clearly if one expresses eqns. **??**, **??** and **??** as:

$$\frac{\mathrm{d}\ln P_{obs}(\mathbf{T}(\boldsymbol{\theta}))}{\mathrm{d}\boldsymbol{\theta}_i} = \frac{\partial \ln P_{obs}}{\partial \mathbf{T}_j}\frac{\partial \mathbf{T}_j}{\partial \boldsymbol{\theta}_i} \tag{4.14}$$

where $\mathbf{T}_i = \{\ln P, \ln H, \ln D_A, \ln f, \ln b\}$ and $\partial P_{obs}/\partial \mathbf{T}_i = \zeta$ from eqn. **??**. The Jacobian is then simply:

$$J = \frac{\partial \mathbf{T}_j}{\partial \boldsymbol{\theta}_i} \tag{4.15}$$

The Fisher matrix

$$\tilde{F}_{ab} \approx (\zeta \otimes \zeta)_{ab} \approx \frac{\partial \ln P_{obs}}{\partial \mathbf{T}_a}\frac{\partial \ln P_{obs}}{\partial \mathbf{T}_b} \tag{4.16}$$

formed in the intermediate variables $\boldsymbol{T}$ can be transfomed to the usual one F by calculating:

$$F_{ab} \approx \frac{\mathrm{d}\ln P_{obs}}{\mathrm{d}\boldsymbol{\theta}_a} \frac{\mathrm{d}\ln P_{obs}}{\mathrm{d}\boldsymbol{\theta}_b} \approx \frac{\partial\ln P_{obs}}{\partial\mathbf{T}_j} \frac{\partial\mathbf{T}_j}{\partial\boldsymbol{\theta}_a} \frac{\partial\ln P_{obs}}{\partial\mathbf{T}_j} \frac{\partial\mathbf{T}_j}{\partial\boldsymbol{\theta}_b} = J^T \tilde{F} J \quad (4.17)$$

In the praxis however, for calculating the full Fisher matrix, one interchanges the first element of ζ by the first element $\partial\boldsymbol{F}_1/\partial\boldsymbol{\theta}_i$ (corresponding to the derivatives of the power spectrum $P(k,z)$) since one needs to integrate values in k and z. That is why one uses the vector Θ from eqn. **??**. In this case the Jacobian and the $\tilde{F}$ do not look like the ones presented above. This is however, mathematically equivalent at this point.

4.4.1.4 The Alcock-Paczynski-Effect

The Alcock-Paczynski-effect (AP) reiles on the fact that the scales k and the direction cosines μ are changed by geometrical factors of distance, when the cosmological parameters are changed. This means that k and μ depend on $H(z)$ and $D_A(z)$ and therefore are also indirectly functions of the cosmological parameters θ_i. The AP formulas relating the fiducial values of k_{fid} and μ_{fid} to their transformed values are:

$$k_{AP} = R_{AP}(\mu;\theta) k_{fid} \quad (4.18)$$

$$\mu_{AP} = \frac{H(z;\theta)}{H(z;\theta_{fid})} \frac{\mu_{fid}}{R_{AP}(\mu;\theta)} \quad (4.19)$$

where the geometrical function R_{AP} is defined as:

$$R_{AP}(\mu;\theta) = \sqrt{\frac{[D_A(z;\theta)H(z;\theta)\mu_{fid}]^2 - [(D_A(z;\theta_{fid})H(z;\theta_{fid})]^2(\mu_{fid}-1)}{[D_A(z;\theta)H(z;\theta_{fid})]^2}}$$

$$(4.20)$$

The last two terms of eqn. **??** come from the fact that now $k = k(H(z;\theta), D_A(z;\theta))$ and $\mu = k(H(z;\theta), D_A(z;\theta))$, so that one has to use the chain rule for the derivative of $P_{obs}(k,\mu,z;\theta)$:

$$\frac{\partial\ln P_{obs}\left(\bar{z},k,\mu;H(z);\theta_i\right)}{\partial\ln H(z)} = \frac{\partial\ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial\ln H(z)} \quad (4.21)$$

$$+ \frac{\partial\ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial\mu} \frac{\partial\mu}{\partial\ln H(z)} + \frac{\partial\ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial k} \frac{\partial k}{\partial\ln H(z)}$$

and similarly for the dependence on $D_A(z)$.

Now we can write down explicitly the intermediate derivatives (evaluated at the fiducial value as usual):

$$\frac{\partial\ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial k} = \frac{\partial\ln P\left(\bar{z},k;\theta_i\right)}{\partial k} \quad (4.22)$$

$$\frac{\partial\ln P_{obs}\left(\bar{z},k,\mu;\theta_i\right)}{\partial\mu} = \frac{4\beta(z)\mu}{1+\beta(z)\mu^2} \quad (4.23)$$

and the derivatives of k and μ with respect to $\ln D_A$ and $\ln H$ are:

$$\frac{\partial \mu}{\partial \ln D_A(z)} = -\mu(\mu^2 - 1) \tag{4.24a}$$

$$\frac{\partial \mu}{\partial \ln H(z)} = -\mu(\mu^2 - 1) \tag{4.24b}$$

$$\frac{\partial k}{\partial \ln D_A(z)} = k(\mu^2 - 1) \tag{4.24c}$$

$$\frac{\partial k}{\partial \ln H(z)} = k\mu^2 \tag{4.24d}$$

The interesting thing about eqns.**??** is that one can see that when evaluating the derivative of P_{obs} w.r.t a cosmological parameter, the scales k and the direction cosine angles μ get mixed, giving a very powerful probe of cosmology. Using this, the vectors that form the Fisher matrix (either ζ or Θ, depending on the choice) have to be extended in their indices corresponding to $\ln D_A$ and $\ln H$. So that they are now more complicated:

$$\Theta = \left\{ \frac{\partial \ln P(k, \bar{z})}{\partial \theta_i}, 1 + \frac{4\beta(z)\mu}{1 + \beta(z)\mu^2}(-\mu(\mu^2 - 1)) + \frac{\partial \ln P(\bar{z}, k; \theta_i)}{\partial k} k\mu^2, \right.$$
$$\left. -2 + \frac{4\beta(z)\mu}{1 + \beta(z)\mu^2}(-\mu(\mu^2 - 1)) + \frac{\partial \ln P(\bar{z}, k; \theta_i)}{\partial k} k(\mu^2 - 1), \frac{2\beta(\bar{z})\mu^2}{1 + \beta(\bar{z})\mu^2}, \frac{2}{1 + \beta(\bar{z})\mu^2} \right\} \tag{4.25}$$

However, using the procedure described above, one can see that the Fisher matrix will have the same dimensions and that the Jacobian will be the same as in eqn. **??**.

4.4.2 Marginalization

When using the form of the observed power spectrum presented before, it is not always possible to "project back" the matrix $\tilde{F}$ into the matrix F which contains only fundamental cosmological parameters. This is the case for the bias or the extra shot noise, since there we do not know how the derivatives $\partial \ln b(z)/\partial \theta_i$ or $\partial P_s(z)/\partial \theta_i$ look like, since those are observational and/or phenomenological quantities which do not yet have a model in terms of fundamental cosmological parameters. Therefore, these terms will always remain and cannot be expressed as a function of cosmological parameters and have to be either fixed or marginalized over. In terms of the Fisher matrix F_{ij}, the marginalization is perfomed easily by removing from the inverse F_{ij}^{-1} all rows and columns corresponding to the index of the quantity to marginalize. More about this will be explained later on.

5.2 The non-linear standard equations in Fourier space

For studying large scale structure formation we will treat the Dark Matter distribution as a perfect fluid coupled to gravity, described by the continuity, Euler and Poisson's equations. This amounts to neglecting higher moments of the Vlasov equation, such as the stress tensor and velocity dispersions **bernardeau_large-scale_2001** This is equivalent to the single stream approximation and is one of the main limitations of Eulerian perturbation theory, since the theory breaks down as soon as shell crossing and multi-streaming start being important.

In the Einstein frame we have the following fluid equations for a general modification of gravity or a coupling to other scalar degrees of freedom **pietroni_flowing_2008**

$$\frac{\partial \delta_c}{\partial \tau} + \nabla \cdot \left[(1 + \delta_c) \, \mathbf{v} \right] = 0 \tag{5.1}$$

$$\frac{\partial \mathbf{v}}{\partial \tau} + \mathcal{H}(\mathbf{v} + [\mathcal{A}\mathbf{v}]) + (\mathbf{v} \cdot \nabla) \, \mathbf{v} = -\nabla \Psi \tag{5.2}$$

$$\nabla^2 \Psi = \frac{3}{2} \mathcal{H}^2 \Omega_c(\tau) \left(\delta_c + [\mathcal{B}\delta_c] \right) \tag{5.3}$$

Here τ is the conformal time, $\delta_c(\mathbf{x}, \tau)$ and $\mathbf{v}(\mathbf{x}, \tau)$ are respectively the matter density contrast and the peculiar velocity, $\mathcal{H} = \mathrm{d}\log a / \mathrm{d}\tau$ is the conformal Hubble parameter, $\Psi(\mathbf{x}, \tau)$ the gravitational potential and the functions $\mathcal{A}(\mathbf{x}, \tau)$ and $\mathcal{B}(\mathbf{x}, \tau)$ are general functions of space and time that parametrize different cosmologies, when particles' geodesics are modified, i.e. the Poisson and Euler equations. This can happen due to couplings with a scalar field

or more general modifications of gravity (MG), such as any Horndeski theory or massive bigravity theories **amendola_observables_2012** However, in the Jordan frame (where most MG theories are formulated) the Euler equation is not modified and there is only a space-time dependent modification to the Poisson equation, which can be expressed as in eqn. 2.6 once we go to Fourier space. In this work $\Omega_m(\tau) \equiv \Omega_c(\tau)$ are the time functions representing the cold dark matter (CDM) or the full matter density of the Universe, since we are not considering baryonic matter nor non-universal couplings.

The last term in the left hand side of eqns. 5.1 and 5.2 is what causes the nonliniearities in the evolution of the fluid. This can be seen in Fourier space as a mode-mode coupling or expressed as a nonlocality of the equations. This is the property that describes how a specific Fourier mode is able to depend on another mode at a different wave vector. We now go to Fourier space and will express equations 5.1-5.3 in a compact form introduced by **scoccimarro_new_2000**

The density is a scalar degree of freedom and the velocity can be decomposed such that:

$$\mathbf{v}(\mathbf{k}) = \mathbf{v}_\theta(\mathbf{k}) + \mathbf{v}_\omega(\mathbf{k}) \tag{5.4}$$

where:

$$\mathbf{k} \cdot \mathbf{v}_\omega(\mathbf{k}) = 0$$
$$\mathbf{k} \times \mathbf{v}_\theta(\mathbf{k}) = 0$$

According to linear theory the vorticity component $\mathbf{v}_\omega(\mathbf{k})$ decays with the expansion of the Universe as a^{-1}, so if we assume non-vortical initial conditions, we can neglect this term and look only at the velocity divergence $\theta = i\mathbf{k} \cdot \mathbf{v}$, which is now a scalar function. Inverting this last relation to get: $\mathbf{v} = -\frac{i\mathbf{k}}{k^2}\theta$, allows us to perform the Fourier transforms explicitly:

$$FT\left\{\nabla \cdot (\delta_m \mathbf{v})\right\} = +i\mathbf{k} \int \mathrm{d}^3q \mathrm{d}^3p\, \delta_D(\mathbf{p} + \mathbf{q} - \mathbf{k}) \frac{-i\mathbf{p}}{p^2} \delta_m(\mathbf{q}, \tau)\theta(\mathbf{p}, \tau)$$

$$= \int \mathrm{d}^3q \mathrm{d}^3p\, \delta_D(\mathbf{k} - \mathbf{p} - \mathbf{q}) \underbrace{\frac{(\mathbf{p} + \mathbf{q}) \cdot \mathbf{p}}{p^2}}_{\alpha(\mathbf{p}, \mathbf{q})} \delta_m(\mathbf{q}, \tau)\theta(\mathbf{p}, \tau)$$

$$FT\left\{\nabla \cdot [(\mathbf{v} \cdot \nabla) \cdot \mathbf{v}]\right\} = i\mathbf{k} \cdot \int \mathrm{d}^3q \mathrm{d}^3p\, \delta_D(\mathbf{q} + \mathbf{p} - \mathbf{k}) \left(\frac{-i\mathbf{q}}{q^2} \cdot i\mathbf{p}\right) \frac{-i\mathbf{p}}{p^2} \theta(\mathbf{q}, \tau)\theta(\mathbf{p}, \tau)$$

$$= \mathbf{k} \cdot \int \mathrm{d}^3q \mathrm{d}^3p\, \delta_D(\mathbf{k} - \mathbf{q} - \mathbf{p}) \left(\frac{\mathbf{p} \cdot \mathbf{q}}{p^2 q^2}\right) \mathbf{p}\, \theta(\mathbf{q}, \tau)\theta(\mathbf{p}, \tau)$$

$$= \int \mathrm{d}^3q \mathrm{d}^3p\, \delta_D(\mathbf{k} - \mathbf{q} - \mathbf{p}) \underbrace{\frac{(\mathbf{p} \cdot \mathbf{q})^2 \mathbf{p} \cdot \mathbf{q}}{2p^2 q^2}}_{\beta(\mathbf{q}, \mathbf{p})} \theta(\mathbf{q}, \tau)\theta(\mathbf{p}, \tau)$$

where in the last step we used the symmetry between $\mathbf{p}$ and $\mathbf{q}$. The terms marked with an underbrace, are the ones responsible for the mode-mode coupling:

$$\alpha(\mathbf{q}, \mathbf{p}) = \frac{(\mathbf{p} + \mathbf{q}) \cdot \mathbf{q}}{q^2} = \alpha(-\mathbf{q}, -\mathbf{p}); \ \beta(\mathbf{q}, \mathbf{p}) = \frac{(\mathbf{p} + \mathbf{q})^2 \mathbf{p} \cdot \mathbf{q}}{2p^2 q^2} = \beta(-\mathbf{q}, -\mathbf{p})$$

(5.5)

5.2.0.1 The field notation

In the perturbation theory literature **bernardeau_large-scale_2001; crocce_renormalized_2005; pietroni_flowing_2008** eqns. 5.1-5.3 are written in a more compact way (also called field notation):

$$\partial_\eta \varphi_a(\mathbf{k}, \eta) = -\Omega_{ab}(\mathbf{k}, \eta) \varphi_b(\mathbf{k}, \eta) + e^\eta \gamma_{abc}(\mathbf{k}, -\mathbf{p}, -\mathbf{q}) \varphi_b(\mathbf{p}, \eta) \varphi_c(\mathbf{q}, \eta)$$ (5.6)

Where the field doublet is defined as:

$$\varphi_a(\mathbf{k}, \eta) = e^{-\eta} \begin{pmatrix} \delta_m(\mathbf{k}, \eta) \\ -\theta(\mathbf{k}, \eta)/\mathcal{H} \end{pmatrix}$$

(5.7)

and we define a new time variable which will prove to be very convenient in this notation

$$\eta \equiv \log \frac{a}{a_{in}}$$

On the l.h.s. of eqn. 5.6 the second term represents all the nonlinearities and non-localities, if we neglect this term we go back to linear perturbation theory. The γ_{abc} functions in this formalism can be understood as interaction vertices and its only non-vanishing components are precisely given by the mode-mode coupling functions 5.5 :

$$\gamma_{121}(\mathbf{k}, \mathbf{p}, \mathbf{q}) = \frac{1}{2} \delta_D(\mathbf{k} + \mathbf{p} + \mathbf{q}) \alpha(\mathbf{p}, \mathbf{q}) \quad \gamma_{121}(\mathbf{k}, \mathbf{q}, \mathbf{p}) = \gamma_{112}(\mathbf{k}, \mathbf{p}, \mathbf{q})$$ (5.8)

$$\gamma_{222}(\mathbf{k}, \mathbf{p}, \mathbf{q}) = \delta_D(\mathbf{k} + \mathbf{p} + \mathbf{q}) \beta(\mathbf{p}, \mathbf{q})$$

in this notation and throughout this work, an integration over $\mathbf{p}, \mathbf{q}$ is understood and $\mathbf{k}$ is always the "external" momentum. The integral signs will be added only when there could be a confusion.

Due to mode-mode coupling, there is a loss of information about the initial conditions in the limit of high-k, since density perturbations get mixed **crocce_memory_2006** This has as a consequence that highly-nonlinear corrections to the power spectrum become cosmology-independent in a rough way.

The information about the cosmological background is contained in:

$$\Omega_{ab}(\mathbf{k}, \eta) = \begin{pmatrix} 1 & -1 \\ -\frac{3}{2}\Omega_m(\eta)(1 + \mathcal{B}(\mathbf{k}, \eta)) & 2 + \frac{\mathcal{H}'}{\mathcal{H}} + \mathcal{A}(\mathbf{k}, \eta) \end{pmatrix}$$

(5.9)

Where we have the usual definitions: $\mathcal{H} = aH$, $ad\tau = dt$, $a' = \frac{da}{d\ln a} = a$, $\frac{\mathcal{H}'}{\mathcal{H}} = \frac{H'}{H} + 1$, where $' := \frac{d}{d\ln a}$ and $N \equiv \ln a$ is what is typically called the e-foldings time.

For details on how to go back to the usual fluid equations 5.1-5.3 in Fourier space starting from the field equation 5.6, see Appendix **??**.

Equation 5.6 is the starting point for all renormalization and resummation methods **crocce_renormalized_2005**; **bernardeau_evolution_2013**; **bernardeau_constructing_2012**; **valageas_matter_2013**; **anselmi_nonlinear_2012**; **anselmi_next–leading_2010** The linear part can be easily solved and the function relating the initial primordial density perturbations to the final one, is called the linear propagator and will be studied in section 5.2.1. The nonlinear part, cannot be solved exactly analytically, nor numerically. But a perturbative approach using all tools from Quantum Field Theory can be used to regularize its divergences which are caused by the fact that the density perturbations (which is at the same time the perturbation variable) grows with time and increasing wave vector. For this part we will use the resummation technique of **anselmi_nonlinear_2012** and this will be explained in detail in section 5.3.

Renormalized perturbation theory (RPT) can help in finding the evolution of the nonlinear power spectrum at small scales and late times, but even if we could calculate exactly its result at all loop orders, there are still intrinsic limitations given by the starting equations 5.1-5.3. Apart from neglecting vorticity in the later stages of evolution, the initial equations are derived in the single-stream-approximation. This means that at a single point in space, there can be only one velocity direction. This clearly breaks down in the virialization regime and even before. The RPT approach can be extended and improved by including these other sources of density power into the equations in an effective way, see the discussion in **manzotti_coarse_2014**; **pietroni_coarse-grained_2011** and recent results in the effective field theory of large scale structures **baumann_cosmological_2012**; **pajer_renormalization_2013**; **senatore_ir-resummed_2014**; **carrasco_effective_2012**

5.2.1   Solving for the general scale dependent linear propagator

As was explained above, in eqn. 5.6 the non-linearity of the Vlasov-Poisson system of equations is fully encoded in the vertex γ_{abc} which represents the mode-mode coupling. Without this term, we recover the linear equation:

$$\partial_\eta \varphi_a(\mathbf{k}, \eta) = -\Omega_{ab}(\mathbf{k}, \eta)\varphi_b(\mathbf{k}, \eta) \tag{5.10}$$

which is valid for a fully scale and time dependent Ω_{ab}.

The linear propagator is just the function that connects the initial density perturbations with the final ones, or in other words solves the above equation **crocce_renormalized_2005** If this equation has solutions of the form **pietroni_flowing_2008**

$$\varphi_{sol}(\mathbf{k}, \eta) = \begin{pmatrix} 1 \\ f(\mathbf{k}, \eta) \end{pmatrix} \varphi(\mathbf{k}, \eta)$$

then we can find an equation that describes the evolution of the growth of perturbations.

For the index $a = 1$:

$$\partial_\eta \varphi = -\Omega_{11}\varphi - \Omega_{12}f\varphi = -(\Omega_{11} + \Omega_{12}f)\varphi \tag{5.11}$$

For the index $a = 2$:

$$\partial_\eta(f\varphi) = f\partial_\eta\varphi + \varphi\partial_\eta f = -\Omega_{21}\varphi - \Omega_{22}f\varphi$$

$$\Rightarrow \partial_\eta f = \Omega_{12}f^2 + (\Omega_{11} - \Omega_{22})f - \Omega_{21} \tag{5.12}$$

$$\Rightarrow \partial_\eta f = \Omega_{12}(f - \bar{f}_+)(f - \bar{f}_-) \tag{5.13}$$

Equation 5.12 is what we usually know as the growth rate equation for $f = \mathrm{d}\ln D/\mathrm{d}\ln a$, being D the growth factor of density perturbations and in this general case it can have a time and scale dependent solution.

The zeros of eqn. 5.13 are given by:

$$\bar{f}_\pm(\mathbf{k},\eta) = \frac{(\Omega_{22} - \Omega_{11}) \mp \sqrt{(\Omega_{22} - \Omega_{11})^2 + 4\Omega_{21}\Omega_{12}}}{2\Omega_{12}} \tag{5.14}$$

The solution of eqns. 5.11 and 5.13 is then given by:

$$\varphi(\eta) = e^{-\int_{\eta'}^\eta (\Omega_{11} + \Omega_{12}f)\mathrm{d}x}\varphi(\eta')$$

$$f(\eta)\varphi(\eta) = e^{-\int_{\eta'}^\eta (\Omega_{21} + \Omega_{22}f)\mathrm{d}x}f(\eta')\varphi(\eta')$$

$$= e^{-\int_{\eta'}^\eta (\Omega_{11} + \Omega_{12}f)\mathrm{d}x}\varphi(\eta')f(\eta')\frac{f(\eta)}{f(\eta')}$$

One can identify the basis solutions by setting their initial conditions as:

$$f_\pm^{in} = \bar{f}_\pm(\mathbf{k},\eta_i)$$

where η_i is an initial time that can be set at high redshift where the Universe is approximately Einstein-deSitter (E-dS) or strongly matter dominated.

For E-dS, $\Omega_m = 1$ we have very simple background quantities: $\mathcal{H}'\backslash\mathcal{H} = -1/2 - 3w_{eff}/2 = -1/2$, so that the Ω_{ab} from equation 5.9 is simply:

$$\Omega_{ab} = \begin{pmatrix} 1 & -1 \\ -\frac{3}{2} & \frac{3}{2} \end{pmatrix}$$

which gives the following initial conditions for the growing u and decaying v modes:

$$u_a = \begin{pmatrix} 1 \\ f_+^{in} \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

$$v_a = \begin{pmatrix} 1 \\ f_-^{in} \end{pmatrix} = \begin{pmatrix} 1 \\ -\frac{3}{2} \end{pmatrix}$$

The growing mode will be the mode of interest that we will use in section 5.3, when we want to calculate the evolution of the power spectrum.

The instantaneous projectors on the two basis solutions are defined as:

$$\mathbf{M}^+(\mathbf{k}, \eta) \begin{pmatrix} 1 \\ f_+(\mathbf{k}, \eta) \end{pmatrix} = \begin{pmatrix} 1 \\ f_+(\mathbf{k}, \eta) \end{pmatrix}$$

$$\mathbf{M}^+(\mathbf{k}, \eta) \begin{pmatrix} 1 \\ f_-(\mathbf{k}, \eta) \end{pmatrix} = 0$$

$$\mathbf{M}^-(\mathbf{k}, \eta) \begin{pmatrix} 1 \\ f_-(\mathbf{k}, \eta) \end{pmatrix} = \begin{pmatrix} 1 \\ f_-(\mathbf{k}, \eta) \end{pmatrix}$$

$$\mathbf{M}^-(\mathbf{k}, \eta) \begin{pmatrix} 1 \\ f_+(\mathbf{k}, \eta) \end{pmatrix} = 0$$

The growing projector can be written explicitly by subtracting the decaying projector from the unity matrix:

$$\mathbf{M}^+(\mathbf{k}, \eta) = \mathbb{K} - \mathbf{M}^-(\mathbf{k}, \eta) = \frac{1}{f_- - f_+} \begin{pmatrix} f_- & -1 \\ f_- f_+ & -f_+ \end{pmatrix}$$

For the Einstein-deSitter case, the projectors do not evolve in time, since u_a and v_a are constant, and they are given by:

$$\mathbf{M}^+ = \frac{1}{5} \begin{pmatrix} 3 & 2 \\ 3 & 2 \end{pmatrix}$$

$$\mathbf{M}^- = \frac{1}{5} \begin{pmatrix} 2 & -2 \\ -3 & 3 \end{pmatrix}$$

The linear propagator is defined as the operator giving the linear evolution of the field φ_a, or in other words, solves eqn.5.10 :

$$\varphi_a(\mathbf{k}, \eta) = g_{ab}(\mathbf{k}, \eta, \eta') \varphi_b(\mathbf{k}, \eta)$$

and it has to fulfill following properties:

$$\partial_\eta g_{ab}(\mathbf{k}, \eta, \eta') = -\Omega_{ac}(\mathbf{k}, \eta) \cdot g_{cb}(\mathbf{k}, \eta, \eta')$$

$$\lim_{\eta' \to \eta} g_{ab}(\mathbf{k}, \eta, \eta') = \mathbb{K}_{ab}$$

$$g_{ab}(\mathbf{k}, \eta, \eta') \cdot g_{bc}(\mathbf{k}, \eta', \eta'') = g_{ac}(\mathbf{k}, \eta, \eta'')$$

Using these properties and the projectors, the propagator can be written in general as:

$$g(\mathbf{k}, \eta, \eta') = \Theta(\eta - \eta') \left[e^{-\int_{\eta'}^{\eta}(\Omega_{11}+\Omega_{12}f_+)dx} \begin{pmatrix} 1 & 0 \\ 0 & \frac{f_+(\mathbf{k},\eta)}{f_+(\mathbf{k},\eta')} \end{pmatrix} \mathbf{M}^+(\mathbf{k}, \eta') \right.$$

$$\left. + e^{-\int_{\eta'}^{\eta}(\Omega_{11}+\Omega_{12}f_-)dx} \begin{pmatrix} 1 & 0 \\ 0 & \frac{f_-(\mathbf{k},\eta)}{f_-(\mathbf{k},\eta')} \end{pmatrix} \mathbf{M}^-(\mathbf{k}, \eta') \right] \tag{5.15}$$

In the E-dS case, this would reduce to simply (since there is no k-dependence in any quantity and the growing mode is constant):

$$g(\eta, \eta') = \Theta(\eta - \eta') \left[\frac{1}{5} \begin{pmatrix} 3 & 2 \\ 3 & 2 \end{pmatrix} + \frac{1}{5} \begin{pmatrix} 2 & -2 \\ -3 & 3 \end{pmatrix} e^{-5/2(\eta-\eta')} \right]$$

Using the same procedure, we will calculate the linear propagator for the Horndeski case, in which the growth factor D is now scale and time dependent. Then the linear propagator can be used to calculate its fully nonlinear renormalized version, which then is a crucial ingredient of the evolution equation in section 5.3.

5.2.2 The linear propagator in the Horndeski case

Using eqn. 2.6 as the modification of the Poisson equation we can write the general Ω_{ab} matrix as:

$$\Omega_{ab}(\mathbf{k}, \eta) = \begin{pmatrix} 1 & -1 \\ -\frac{3\mu(k)\Omega_m(\eta)}{2} & \frac{\mathcal{H}'}{\mathcal{H}} + 2 \end{pmatrix} \qquad (5.16)$$

in this case, the initial conditions from eqn.5.14 are:

$$\begin{aligned} f^{in}_- &= -\frac{1}{2}(\Sigma + \omega) \\ f^{in}_+ &= \frac{1}{2}(\Sigma - \omega) \end{aligned} \qquad (5.17)$$

where $\omega = 1 + \frac{\mathcal{H}'}{\mathcal{H}} = \frac{1}{2} - \frac{3}{2}w_{eff}$ and $\Sigma = \sqrt{6Y\Omega_m + \omega^2}$ are quite general functions of scale and time. Inserting this into eqn.5.15, one can find the most general form of the propagator for the Horndeski theory. However, this is not so practical, since we would have to solve for a scale and time dependent growth rate f and evaluate the $\mathcal{H}$ function at each step.

For models which are close to ΛCDM, it is more convenient to change the time variable from $\eta = \ln\frac{a}{a_{in}}$ to $\mathcal{X} = \ln\frac{D(\tau)}{D(\tau=\tau_{in})}$, where $D(\tau)$ is the growth function usually written as the growing solution of the linear density perturbation equation : $\delta_c(\tau) = D_+(\tau)\delta_c^{in}$. In our case, however, the time variable $\mathcal{X}$ would itself be scale dependent, since the growth rate equation in the Horndeski case is scale dependent, so that $\mathcal{X}(k) = \ln\frac{D(\tau,k)}{D(\tau=\tau_{in},k)}$. Using $\frac{\partial}{\partial \eta} = \frac{d\ln D}{d\ln a}\frac{\partial}{\partial \ln D} = f\frac{\partial}{\partial \mathcal{X}}$, we can rewrite eqns.5.11-5.12 as (where $' := \frac{\partial}{\partial \mathcal{X}}$):

$$f(\mathbf{k}, \mathcal{X})\delta_c'(\mathbf{k}, \mathcal{X}) + \frac{\theta(\mathbf{k}, \mathcal{X})}{\mathcal{H}} + \frac{\mathbf{k} \cdot \mathbf{q}}{q^2}\delta_c(\mathbf{q}, \mathcal{X})\frac{\theta(\mathbf{p}, \mathcal{X})}{\mathcal{H}} = 0 \qquad (5.18)$$

$$f(\mathbf{k}, \mathcal{X})\frac{\theta(\mathbf{k}, \mathcal{X})'}{\mathcal{H}} + \frac{\theta(\mathbf{k}, \mathcal{X})}{\mathcal{H}} + \frac{1}{2}\frac{\mathbf{k}^2\mathbf{q} \cdot \mathbf{p}}{q^2 p^2}\frac{\theta(\mathbf{q}, \mathcal{X})}{\mathcal{H}}\frac{\theta(\mathbf{p}, \mathcal{X})}{\mathcal{H}} = -\frac{3}{2}\Omega_m(\mathcal{X})\mu(\mathbf{k})\mathcal{H}^2\delta_c(\mathbf{k}, \mathcal{X}) \qquad (5.19)$$

The doublet 5.7 can now be redefined as:

$$\tilde{\varphi}_a = \begin{pmatrix} \tilde{\varphi}_1 \\ \tilde{\varphi}_2 \end{pmatrix} = \begin{pmatrix} e^{-\mathcal{X}}\delta_c \\ -e^{-\mathcal{X}}\frac{\theta}{\mathcal{H}f} \end{pmatrix} \qquad (5.20)$$

Substituting in the previous equations the values for δ_c, θ and $\delta_c' = e^{\mathcal{X}}(\varphi_1' + \varphi_1)$, $\theta' = -e^{\mathcal{X}}f(\mathcal{X})\mathcal{H}\left(\tilde{\varphi}_2\left(1 + \frac{f'(\mathcal{X})}{f(\mathcal{X})} + \frac{\mathcal{H}'}{\mathcal{H}}\right) + \tilde{\varphi}_2'\right)$ we get:

$$\tilde{\varphi}_1' + \tilde{\varphi}_1 - \tilde{\varphi}_2 - \alpha e^{\mathcal{X}} \tilde{\varphi}_1 \tilde{\varphi}_2 = 0 \tag{5.21}$$

$$-\tilde{\varphi}_2' - \tilde{\varphi}_2 (1 + \frac{f'}{f} + \frac{1}{f} + \frac{\mathcal{H}'}{\mathcal{H}}) + \beta e^{\mathcal{X}} \tilde{\varphi}_2 \tilde{\varphi}_2 = -\frac{3}{2} \Omega_m \mu \frac{\tilde{\varphi}_1}{f^2}$$

$$\Rightarrow -\tilde{\varphi}_2' - \frac{3}{2} \frac{\Omega_m \mu}{f^2} \tilde{\varphi}_2 + \frac{3}{2} \frac{\Omega_m \mu}{f^2} \tilde{\varphi}_1 + \beta e^{\mathcal{X}} \tilde{\varphi}_2 \tilde{\varphi}_2 = 0 \tag{5.22}$$

where we have omitted for notational simplicity the momentum and time dependence. In the last step we used the growth rate equation $\ddot{\delta}_m + \dot{\delta}_m \left(1 + \frac{\dot{\mathcal{H}}}{\mathcal{H}}\right) = \frac{3}{2} \Omega_m \delta_m \mu$, where in this case an overdot represents a derivative with respect to $\eta = \ln \frac{a}{a_{in}}$, since the $'$-symbol is now reserved for the $\mathcal{X}$ time variable.

Comparing eqns. 5.21-5.22 with 5.6, we get the following Ω matrix:

$$\tilde{\Omega}(\mathbf{k}, \mathcal{X}) = \begin{pmatrix} 1 & -1 \\ -\frac{3}{2} \frac{\Omega_m(\mathcal{X})}{f_+^2(\mathcal{X})} \mu(k) & \frac{3}{2} \frac{\Omega_m(\mathcal{X})}{f_+^2(\mathcal{X})} \mu(k) \end{pmatrix} \tag{5.23}$$

It is of great importance to note that in the Horndeski case, the quantity $\frac{\Omega_m(\mathcal{X})}{f_+^2(\mathcal{X})}$ cannot be approximated to 1 as it is done in LCDM for all times, since in this case it can have a much greater or lower value during structure formation, but more importantly it is scale-dependent through the scale dependence of $\mathcal{X}(k)$. This can be seen clearly in plot ??.

5.2.3 Assuming a constant $\mu \neq 1$ for the 1-loop quantities

Assuming a constant μ different from 1 and the approximation that $\frac{\Omega_m(\mathcal{X})}{f_+^2(\mathcal{X})} = 1$ throughout the history of the Universe (which is valid only for E-dS but turns out to be a good approximation (much more accurately than 1%) for the nonlinear ΛCDM power spectrum), we can follow the steps given above in section 5.2.1 and obtain the initial growing and decaying modes:

$$u_a = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

$$v_a = \frac{-2}{3Y} \begin{pmatrix} 1 \\ -\frac{3Y}{2} \end{pmatrix}$$

and with this the projectors:

$$\mathbf{M}^+ = \frac{1}{2 + 3Y} \begin{pmatrix} 3Y & 2 \\ 3Y & 2 \end{pmatrix}$$

$$\mathbf{M}^- = \frac{1}{2 + 3Y} \begin{pmatrix} 2 & -2 \\ -3Y & 3Y \end{pmatrix}$$

The propagator would then look like:

$$g(\mathcal{X}, \mathcal{X}') = \Theta(\mathcal{X} - \mathcal{X}') \left[\frac{1}{2 + 3Y} \begin{pmatrix} 3Y & 2 \\ 3Y & 2 \end{pmatrix} + \frac{1}{2 + 3Y} \begin{pmatrix} 2 & -2 \\ -3Y & 3Y \end{pmatrix} e^{-\frac{(2+3Y)}{2}(\mathcal{X} - \mathcal{X}')} \right] \tag{5.24}$$

For the rest of this work, eqn. 5.24 will be the linear propagator we will use, even if we are treating more general cases where $\mu(k)$ is an arbitrary function and $\Omega_m/f^2 \neq 1$. This approximation can be justified better in the next section, when we will see that g only enters in the evolution equation of the power spectrum inside the integral of the self-energy and mode-coupling 1-loop quantities, which should contribute only sub-dominantly in the final power spectrum.

5.3 The Evolution Equation for the Power Spectrum

We are interested in solving the general scale and time dependent evolution equation from the resummation method presented in **anselmi_nonlinear_2012** (eqn. 53):

$$
\begin{aligned}
\partial_{\mathcal{X}} \tilde{P}_{ab}(k; \mathcal{X}) = &-\tilde{\Omega}_{ac}(\mathbf{k}; \mathcal{X}) \tilde{P}_{cb}(\mathbf{k}; \mathcal{X}) - \tilde{\Omega}_{bc}(\mathbf{k}; \mathcal{X}) \tilde{P}_{ac}(\mathbf{k}; \mathcal{X}) \\
&+ H_{\mathbf{a}}(k; \mathcal{X}, \mathcal{X}_{in}) \tilde{P}_{\mathbf{a}b}(\mathbf{k}; \mathcal{X}) + H_{\mathbf{b}}(k; \mathcal{X}, \mathcal{X}_{in}) \tilde{P}_{a\mathbf{b}}(\mathbf{k}; \mathcal{X}) \\
&+ \int \mathrm{d}s \left[\tilde{\Phi}_{ad}(k; \mathcal{X}, s) G_{bd}^{eik}(k; \mathcal{X}, s) + G_{ad}^{eik}(k; \mathcal{X}, s) \tilde{\Phi}_{db}(k; \mathcal{X}, s) \right]
\end{aligned}
\tag{5.25}
$$

where $\mathcal{X} = \ln(D(a)/D(a_{in}))$ (notice that in ref. **anselmi_nonlinear_2012** η is the time variable and represents the growth factor). The first line of this equation corresponds to the linear evolution equation of the power spectrum already discussed before. The second and third lines contain the 1PI (one-particle-irreducible) functions, the self-energy Σ_{ab} and the mode-coupling term $\tilde{\Phi}G_{ab}^{AB}$ accounting for the contributions at the large- and small-k limit at 1-loop order.

Massimo: Can you check from eqns. 33-36?

If we transform this equation to $\eta = \ln \frac{a}{a_{in}}$, using the variable transformation $\partial \mathcal{X}/\partial \eta = \frac{\mathrm{d} \ln D(a)}{\mathrm{d} \ln a} = f(\eta)$, where $f(\eta) \equiv f(N(\eta))$ and the relation between N and η is given by $N = \eta + \ln(a_{in})$, we have to transform also the power spectrum since the field has been redefined (see 5.20):

$$
\tilde{P}_{ab} = e^{-2\mathcal{X}(\eta)} e^{2\eta} (\delta_{a1} + \frac{1}{f(\eta)} \delta_{a2})(\delta_{b1} + \frac{1}{f(\eta)} \delta_{b2}) P_{ab}(\eta)
\tag{5.26}
$$

where we can call this transformation Ξ_{ab}:

$$
\tilde{P}_{ab} = \Xi_{ab} P_{ab}(\eta)
$$

and its inverse would be:

$$
\Xi_{ab}^{-1} = e^{2\mathcal{X}(\eta)} e^{-2\eta} (\delta_{a1} + f(\eta)\delta_{a2})(\delta_{b1} + f(\eta)\delta_{b2})
\tag{5.27}
$$

However, eqn. 5.25 is only invariant under the transformation:

$$
\Upsilon_{ab}(\eta) = f(\eta)\Xi_{ab}^{-1} = f(\eta) e^{2\mathcal{X}(\eta)} e^{-2\eta} (\delta_{a1} + f(\eta)\delta_{a2})(\delta_{b1} + f(\eta)\delta_{b2})
\tag{5.28}
$$

since we also have to transform the derivatives and the Ω_{ab} functions.

Inserting these transformations into eqn. 5.25, and generalizing to the case where the growth rate is k-dependent, $f(\eta, k)$, we obtain:

$$\partial_\eta P_{ab}(k;\eta) = -\Omega_{ac}(\mathbf{k};\eta)P_{cb}(\mathbf{k};\eta) - \Omega_{bc}(\mathbf{k};\eta)P_{ac}(\mathbf{k};\eta) \tag{5.29}$$
$$+ [H_\mathbf{a}(k;\mathcal{X}(\eta,k),\mathcal{X}(\eta_{in},k))f(\eta,k)P_{\mathbf{a}b}(k;\eta)$$
$$+ H_\mathbf{b}(k;\mathcal{X}(\eta,k),\mathcal{X}(\eta_{in},k))f(\eta,k)P_{a\mathbf{b}}(k;\eta)]$$
$$+ \Upsilon_{ab}(\eta,k) \times \int \mathrm{d}s \left[\tilde{\Phi}_{ad}(k;\mathcal{X}(\eta,k),s)G_{bd}^{eik}(k;\mathcal{X}(\eta,k),s) + G_{ad}^{eik}(k;\mathcal{X}(\eta,k),s)\tilde{\Phi}_{db}(k;\mathcal{X}(\eta,k),s) \right.$$

The quantities such as $H_\mathbf{a}(k;\eta,\eta_{in})$ and $\tilde{\Phi}_{ad}(k;\eta,s)$, shown in eqns 5.33-5.36, which are actually calculated in the $\mathcal{X}$ variable, are now indirectly a function of η through the relation $\mathcal{X}(\eta) = \ln(D(N(\eta))/D(N(\eta_{in})))$.

The evolution equation as it is written in eqn. 5.25 relies on three different assumptions: the power spectrum is well behaved for $k \to 0$, which is in our cosmology a good assumption, since it behaves just a power law k^n; there is a clear separation of scales between "hard" and "soft" modes, or in other words, the eikonal limit is fulfilled. This means that the modes k we are interesting in are much bigger than the internal coupling modes p, q. The third assumption is of course the single-stream approximation, which is used in all forms of resummed and renormalized perturbation theories in cosmology as was explained already in section 5.2.0.1.

In this work we want to solve eqn. **??** for the simple Horndeski models stated above. We will test two apporaches, first we will include inside the $\Omega_{ac}(\mathbf{k};\eta)$ functions, the full scale and time dependence of the parametrized Horndeski models. These terms will have a dominant effect on the evolution of $P(\mathbf{k})$ and we will calculate the 1-loop integrals using the usual ΛCDM model. Since the $H_\mathbf{a}(k;\eta,\eta_{in})$ and $\tilde{\Phi}_{ab}(k;\eta,s)$ functions are calculated for a scale-dependent growth factor, we will have to test if this scale dependence has a big effect on the result.

As a second approach we will calculate the 1PI functions using the linear Horndeski propagator in the case that μ is a constant different from one. Once these integrals are calculated, we can then solve the evolution equation completely. In this case we have to test how much a change in $\mu(k)$ affects the result, i.e. if assuming a constant μ is a good approximation or not. In the next section we will show the explicit expressions for these integrals.

5.3.1   The 1PI functions in the Horndeski constant $\mu \neq 1$ case

The Horndeski variable is Y for compatibility with the code for now, but it can be changed to μ later on.

Now we give the general expression for for the 1PI functions $\Sigma_{ab}^{(1)}(k;\mathcal{X},\mathcal{X}')$ and $\Phi_{ab}^{(1)}(k;\mathcal{X},\mathcal{X}')$ computed at 1-loop in eRPT. The general expression for $\Sigma_{ab}^{(1)}(k;\mathcal{X},\mathcal{X}')$ is given by:

$$\Sigma_{ab}^{(1)}(k;\mathcal{X},\mathcal{X}') =$$
$$4e^{\mathcal{X}+\mathcal{X}'} \int \mathrm{d}^3q\,\gamma_{acd}(\mathbf{k},-\mathbf{q},\mathbf{q}-\mathbf{k})u_c P^0(q)u_e\gamma_{feb}(\mathbf{k}-\mathbf{q},\mathbf{q},-\mathbf{k})g_{df}(\mathcal{X},\mathcal{X}')$$
$$\tag{5.30}$$

If we insert for g_{ab} the linear propagator from 5.24 and the coupling vertices γ_{abc} from 5.8 we have to perform an the angular integration of d^3q, see Appendix ?? for the explicit terms.

The $H_1(k; \mathcal{X}, -\infty)$, $H_2(k; \mathcal{X}, -\infty)$ functions are a time integration of the $\Sigma^{(1)}_{ab}(k; \mathcal{X}, \mathcal{X}')$ quantities in the internal time from minus infinity to the external time η:

$$H_1(k; \mathcal{X}, -\infty) = \int_{-\infty}^{\eta} \mathrm{d}s \Sigma^{(1)}_{1b}(k; \mathcal{X}, \mathcal{X}') u_b \tag{5.31}$$

$$H_2(k; \mathcal{X}, -\infty) = \int_{-\infty}^{\eta} \mathrm{d}s \Sigma^{(1)}_{2b}(k; \mathcal{X}, \mathcal{X}') u_b \tag{5.32}$$

They have the following form after performing the time integration:

$$H_{1Y}(k; \mathcal{X}, -\infty) = -\frac{\pi k^3 e^{2\mathcal{X}}}{3(3Y+4)} \int \mathrm{d}r \left[16 + 3Y \left(3r^4 - 8r^2 + 1\right) - \frac{9Y}{2r} \left(r^2 - 1\right)^3 \log \left|\frac{1+r}{1-r}\right| \right] P^0(kr) \tag{5.33}$$

$$H_{2Y}(k; \mathcal{X}, -\infty) = -\frac{\pi k^3 e^{2\mathcal{X}}}{3(3Y+4)} \int \mathrm{d}r \left[-\frac{9Y}{r^2} + 9r^2\mu + 4(9Y+4) - \frac{9Y}{2r^3} \left(r^2 - 1\right)^3 \log \left|\frac{1+r}{1-r}\right| \right] P^0(kr) \tag{5.34}$$

The third line of the evoution equation 5.25 contains the mode-coupling function, which is obtained by integrating the counter-term 1-loop quantity:

$$\tilde{\Phi}^{(1)}_{ad}(k; \mathcal{X}, \mathcal{X}') = 2e^{\mathcal{X}+\mathcal{X}'} \int \mathrm{d}^3q \gamma_{acd}(\mathbf{k}, -\mathbf{q}, \mathbf{p}) u_c P^0(q) u_d \tag{5.35}$$

$$\times u_e P^0(p) u_f \gamma_{bef}(\mathbf{k}, -\mathbf{q}, \mathbf{p}) \tag{5.36}$$

where $\mathbf{p} = \mathbf{k} - \mathbf{q}$, together with the renormalized propagator from Crocce-Scoccimarro $\bar{G}^L_{bd}(k; \eta, s)$:

$$\int \mathrm{d}s \left[\tilde{\Phi}_{ad}(k; \mathcal{X}, s) \bar{G}^L_{bd}(k; \mathcal{X}, s) + \bar{G}^L_{ad}(k; \mathcal{X}, s) \tilde{\Phi}_{db}(k; \mathcal{X}, s) \right] = \tilde{\Phi}G^A_{ab}(k; \mathcal{X}) + \tilde{\Phi}G^B_{ab}(k; \mathcal{X}) \tag{5.37}$$

where for all a, b, the B terms are:

$$\tilde{\Phi}G^B_{ab}(k; \mathcal{X}) = u_a u_b y^2 \left(\frac{\sqrt{\pi}}{2} \left(2y^2 + 1\right) \mathrm{Erf}(y) + \left(e^{-y^2} - 2\right) y \right) P^0(k) \tag{5.38}$$

The $\tilde{\Phi}G^B_{ab}(k; \eta)$ expression has to be switched off in the small k-limit since it contains 2-loop expressions valid only at large k, therefore it has to be "filtered" by a momentum-cutoff function:

$$\tilde{\Phi}G^A_{ab}(k; \eta) + \frac{(k/\bar{k})^4}{1 + (k/\bar{k})^4} \tilde{\Phi}G^B_{ab}(k; \eta)$$

The $\bar{k}$ quantity can be set to a reasonable scale at which the large scale expression starts to be applicable, usually we can set here $\bar{k} = 0.2h/\mathrm{Mpc}$. The A terms read (a new variable $W = \frac{3}{2}Y$ has been defined for simplicity):

$$\tilde{\Phi}G_{11}^A = y(\Phi_{11}^{(1)} - \Phi_{11}^{(1)})\mathcal{B}(y^2; W) \tag{5.39}$$
$$+ \frac{\sqrt{\pi}\mathrm{Erf}(y)}{W+1}(\Phi_{11}^{(1)}W + \Phi_{12}^{(1)})$$

$$\tilde{\Phi}G_{12}^A = \frac{y\mathcal{B}_{12}(y^2; W)}{(1+W)^2(2+W)}(\Phi_{12}^{(1)} - \Phi_{22}^{(1)} - W(\Phi_{11}^{(1)} - \Phi_{12}^{(1)})) \tag{5.40}$$
$$+ \frac{\sqrt{\pi}\mathrm{Erf}(y)}{2(W+1)}(W(\Phi_{11}^{(1)} + \Phi_{12}^{(1)}) + \Phi_{12}^{(1)} + \Phi_{22}^{(1)}) \tag{5.41}$$

$$\tilde{\Phi}G_{22}^A = \frac{yW}{(W+1)^2}(\Phi_{22}^{(1)} - \Phi_{12}^{(1)})\mathcal{B}(y^2; W) \tag{5.42}$$
$$+ \frac{\sqrt{\pi}}{(W+1)}\mathrm{Erf}(y)(\Phi_{12}^{(1)}W + \Phi_{22}^{(1)})$$

and where we have used the combination of generalized Hypergeometric functions:

$$\mathcal{B}(y^2; W) = {}_2F_2\left(\frac{1}{2}, 1; \frac{W}{2} + 1, \frac{W}{2} + \frac{3}{2}; -y^2\right)$$
$$+ \frac{W+1}{W+2}{}_2F_2\left(\frac{1}{2}, 1; \frac{W}{2} + \frac{3}{2}, \frac{W}{2} + 2; -y^2\right)$$
$$- \frac{1}{W+2}{}_2F_2\left(1, \frac{3}{2}; \frac{W}{2} + \frac{3}{2}, \frac{W}{2} + 2; -y^2\right)$$

$$\mathcal{B}_{12}(y^2; W) = (2+W){}_2F_2\left(\frac{1}{2}, 1; \frac{W}{2} + 1, \frac{W}{2} + \frac{3}{2}; -y^2\right)$$
$$- {}_2F_2\left(1, \frac{3}{2}; \frac{W}{2} + \frac{3}{2}, \frac{W}{2} + 2; -y^2\right)$$

Assuming a general scale-dependent function $\mu(k)$ would turn out impossible an analaytic calculation of the intermediate quantities, which would render a practical implementation of this method to be numerically prohibitive. Therefore, using the fact that the μ function behaves as a step function in $\log k$, having a well defined minimum and maximum value we can use simply a constant and check its effect on the 1-loop and 2-loop corrections. Besides, in any viable model compatible with observations μ can differ from 1 by about 15-20%. So that we can be sure that the overall effect will be just a perturbation around the LCDM value and should reduce to it in the limit $\mu \to 1$.

Issue: In the LCDM case from Massimo's paper, all three $\tilde{\Phi}G_{ab}^A$ functions can be written using the same combination of Hypergeometric Functions. In this case, this is only possible for $\tilde{\Phi}G_{11}^A$ and $\tilde{\Phi}G_{22}^A$.

5.3.2 Method of implementation

Equation **??** is the final and main equation we want to solve and it represents a differential equation in time, for each external momentum k that we are interested in. This means that if we want to compute the power spectrum on a grid with 100 points in k-space, we need to solve 100 times the same differential equation. That is why parallelism plays an important role here to speed up the computational calulation.

First we compute the linear growth function for a specific Horndeski model, using the linear part of 5.19. With this we obtain the growth rate and the growth factor, which are then used to calculate the loop integrals.

The initial power spectrum is obtained from CAMB and its evaluated at 100 points in k-space. This is used to compute analytically eqns. 5.33, 5.34. These integrals can be stored as long as the cosmological parameters are not modified.

Finally we compute the 5.25 for each k mode in parallel, which using 8 cores on a normal machine, takes about 15 seconds until redshift $z = 0$.

5.4 Numerical approaches

5.4.1 N-body simulations

- The Vlasov-Poisson system can be discretized on a grid and the denisty can be represented with particles

- Particle-Mesh method

- Tree method

- Extraction of information: The power spectrum and Halo catalogs
